- Homework 6

- 6/5

- Final report
- Scuz points

Review: CUG test

- Generate many random graphs
- See if the properties of those graphs
 - match the graph you observed
- If so, you can't reject the null hypothesis

Example: Transitivity

○ $\Pr(X \geq \text{Obs}): 0.036$

○ $\Pr(X \leq \text{Obs}): 0.964$

More transitive than
almost all random
networks

Add WeChat powcoder

Example

- New data set

- Assignment Project Exam Help
 - ps5 social network data set

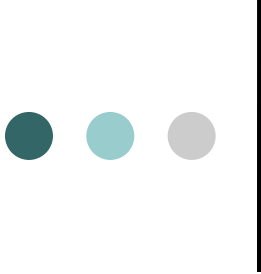

- we'll see this again for ERGM

<https://powcoder.com>

- CUG for

Add WeChat powcoder

- assortativity by color
 - transitivity
 - reciprocity

Quadratic Assignment Procedure (QAP)

- Like CUG

- the goal is to get a non-parametric test of a network property

<https://powcoder.com>

- With QAP

- the goal is to hold network structure fixed
 - and randomly scramble the vertices

Add WeChat powcoder

Example

- Is this graph assortative?
 - (yes)
 - more than one would expect?
- We could take all rearrangements of these vertices
 - look at the assortativity values of all these graphs
- Where does the assortativity of the observed graph
 - lie relative to all of the permutations

Null hypothesis

- The assortativity of the graph could have arisen through random placement of nodes within the network structure
- Combination of
 - distribution of node types
 - particular network configuration

Example

- In this case

- you could try all possibilities
 - only 10 (because order doesn't matter and only need to choose two positions for A and D)

- In a real network

- need to sample from a very large number of possible permutations

In R

network

function

```
myqaptest(gr,  
assortativity.nominal,  
types=V(gr)$type,  
directed=FALSE)
```

function
args

Assignment Project Exam Help

<https://powcoder.com>

Add WeChat powcoder

Note: assortativity.nominal doesn't accept types = 0. Dreaded invalid "types" vector error. Or R crashes totally

Result

```
➤ print.qaptest()
```

QAP Test Results

Estimated p-values:

```
p(f(perm) >= f(d)): 0.101
```

```
p(f(perm) <= f(d)): 1
```

```
> summary.qaptest()
```

QAP Test Results

Estimated p-values:

```
p(f(perm) >= f(d)): 0.101
```

```
p(f(perm) <= f(d)): 1
```

Test Diagnostics:

```
Test Value (f(d)): 0.4666667
```

```
Replications: 1000
```

```
Distribution Summary:...
```

Result

- The assortativity of this network is highly associated with the placement of types in the structure
 - not with the number of nodes of each type
 - or the structure of the network
- This is the only configuration (out of 10) that has assortativity this high

QAP Test

- Allows us to look for effects
 - network structure vs distribution of node attributes
- We can ask
 - is the value associated with this particular network organization “unique” or “rare”
- Cannot use this for network properties
 - like transitivity
 - all vertex permutations will yield the same value

Example

- gr3
 - Assignment? Project Exam Help
 - transitivity?
- QAP test is meaningless
 - <https://powcoder.com>
 - transitivity is a structural property
 - Add WeChat powcoder
 - rearranging the vertices doesn't change it
- Can look at assortativity

Results

- These particular configurations of individuals within the network
 - somewhat disassociative with the color groups
- 84% of random configurations showed greater association

- Estimated p-values:

$p(f(\text{perm}) \geq f(d)) : 0.839$

$p(f(\text{perm}) \leq f(d)) : 0.161$

probability random
configuration will
have a test stat \geq
actual value

Conclusion

- QAP test useful to test configuration properties
 - prime example: assortativity
 - also if you have multiple networks
- Do all re-labelings of nodes show the same properties?
 - network structure fixed
- A “harder” test than CUG
 - we know networks aren’t random
